

An economy of AI creators

Project brief and decision questions. Prepared from HALO_Agent_Economy_Concept.pdf; this is a planning document, not a finalized specification.

The project in one sentence

HALO proposes a network of persistent AI agents that create content, build communities and launch tokens, with each agent operating its own token ecosystem connected to \$HALO.

The three layers

Creation token - for example, \$DOG. A token launched by an agent around a specific narrative or project. The concept pairs it with the creator's agent token: \$DOG / \$FRED.

Agent token - for example, \$FRED. A market asset associated with Fred's identity, reputation and ecosystem. The concept pairs it with \$HALO: \$FRED / \$HALO.

Platform token - \$HALO. The common asset connecting agent economies. The intended thesis is exposure to growth and activity across the network.

What agents are intended to do

Maintain identities and niches; discover narratives; generate images and posts; interact with communities; launch new coins; and build reputations over multiple launches. The long-term vision also includes competition and collaboration between agents.

Why someone would participate

The concept offers three choices: back an individual creation, back the agent behind many creations, or back the broader platform. Its defining idea is a lasting creator identity that connects successive launches.

What is established versus unresolved

Established in the concept: the three-layer structure, trading-pair hierarchy, persistent agents and intended growth loop.

Not specified: token-holder rights, fees, value distribution, liquidity funding, supply, launch rules, chain, technical architecture, operating controls, team, budget and timeline.

How the concept fits together

The example below describes the proposed structure. It does not imply an implemented product or guaranteed economic outcomes.

Example: Fred creates an ecosystem

- 1. Create Fred.** Give the agent a persistent identity, an animal-themed niche and the tools needed to operate.
- 2. Introduce \$FRED.** Establish Fred's agent token and its trading pair with \$HALO.
- 3. Launch creations.** Fred creates \$DOG, \$CAT or other narrative tokens, each paired with \$FRED.
- 4. Build an audience.** Fred publishes content and interacts with users. Successful launches may strengthen his reputation and attract further activity.
- 5. Repeat across agents.** Multiple agents develop separate communities and token ecosystems, connected through \$HALO.

The intended growth loop

More agents lead to more creations; creations attract attention and trading; successful agents attract more participation; that activity may increase use of \$HALO and support further platform growth. This is the concept's hypothesis, not a demonstrated result.

The central economic question

What precisely connects successful creations to value for \$FRED holders, and successful agents to value for \$HALO holders? The document specifies trading pairs but does not define revenue sharing, ownership rights or a distribution mechanism. Those must be explicit before describing either token as broad economic exposure.

Mechanics that need a written specification

Trade route: how a user enters and exits each token, and whether intermediate conversions happen automatically.

Liquidity: who funds pools, who controls liquidity positions and how exits are supported.

Value distribution: where launch fees, trading fees or other revenue go.

Supply: issuance, allocations, vesting and any minting authority.

Failure: what happens to holders when an agent stops or a creation fails.

Source note: the original concept itself identifies utility, transparent mechanics and meaningful liquidity design as necessary for a sustainable version of the project.

Decisions to answer first

These are my highest-priority questions for the project owner. Answers would determine the product, economics and first build.

1. What is the first user experience?

Is HALO primarily an agent discovery app, a token launch platform, an entertainment network, or a place to create your own agent? Who is the first target user?

2. Who creates and owns the agents?

Does the HALO team launch every agent, can anyone create one, or are creators approved? Who controls its identity, wallet and configuration?

3. What does holding each token actually provide?

For \$HALO and agent tokens separately, is the benefit access, governance, a defined fee allocation, another utility, or only market exposure? Which rights are explicitly absent?

4. How does money flow through the system?

What fees exist, who pays them, and who receives them? What mechanism, if any, links a successful \$DOG launch to \$FRED and \$HALO holders?

5. How are launches and liquidity funded?

Who supplies the initial assets for \$FRED / \$HALO and \$DOG / \$FRED pools? Who controls that liquidity, and what prevents an ecosystem from running out of operating funds?

6. How autonomous should agents be?

Can agents publish, deploy tokens and spend funds on their own? Which actions need human approval, and what limits and pause controls apply?

7. Why will people keep returning?

Beyond trading new coins, what recurring value do agents provide: entertainment, useful services, community participation, games or something else?

8. What counts as a successful first version?

What is the smallest demonstration worth launching, what budget and timeline are available, and which measures would justify expanding it?

Further questions & next step

Open implementation questions, followed by a proposed planning sequence. Recommendations on this page are additions to the source concept.

Product and technical questions

Network: which chain and token standards will be used? SOL appears as a comparison in the source; a deployment chain is not confirmed.

Agent runtime: which models, hosting, memory and social integrations are needed? Who pays ongoing inference and publishing costs?

Wallet experience: will users connect an existing wallet or use an embedded one? How will balances, routes and transaction costs be shown?

Launch lifecycle: who may launch, how often, with what supply and allocations, and under what retirement or shutdown rules?

Trust and operating questions

Reputation: what makes an agent credible, and how will genuine participation be distinguished from artificial activity?

Controls: who can pause an agent, change its instructions or recover compromised access?

Transparency: which wallets, allocations, fees and agent actions will users be able to inspect?

Launch scope: which countries and users will be served, and who will obtain the relevant legal review before a public token launch?

Suggested first planning sequence

- 1. Resolve the eight priority questions.** Turn answers into a short product and economics specification.
- 2. Map one complete example.** Follow a user through acquiring \$DOG, paying costs and selling; identify every asset movement and fee recipient.
- 3. Demonstrate one agent in a sandbox.** Show identity, content generation, a simulated launch and a visible action history with human controls.
- 4. Test the expansion criteria.** Evaluate repeat engagement, operating cost, agent reliability and the proposed liquidity mechanics before adding many agents.

Project status

Concept defined. Economic design, implementation scope, resources and launch criteria remain open. No chain, fee rate, supply, delivery date or token-holder entitlement is assumed in this brief.

Source: HALO_Agent_Economy_Concept.pdf, 4 pages, supplied by the project owner. Sections 1-9 establish the vision and structure; section 10 states the economic caveat. No external claims or market validation have been added.
